# Overview

CircleCI Server is a modern continuous integration and continuous delivery (CI/CD) platform installable inside your private cloud or data center. Refer to the [Changelog](#) for what's new in this CircleCI Server release.

CircleCI Server v2.17 uses the CircleCI 2.0 architecture.

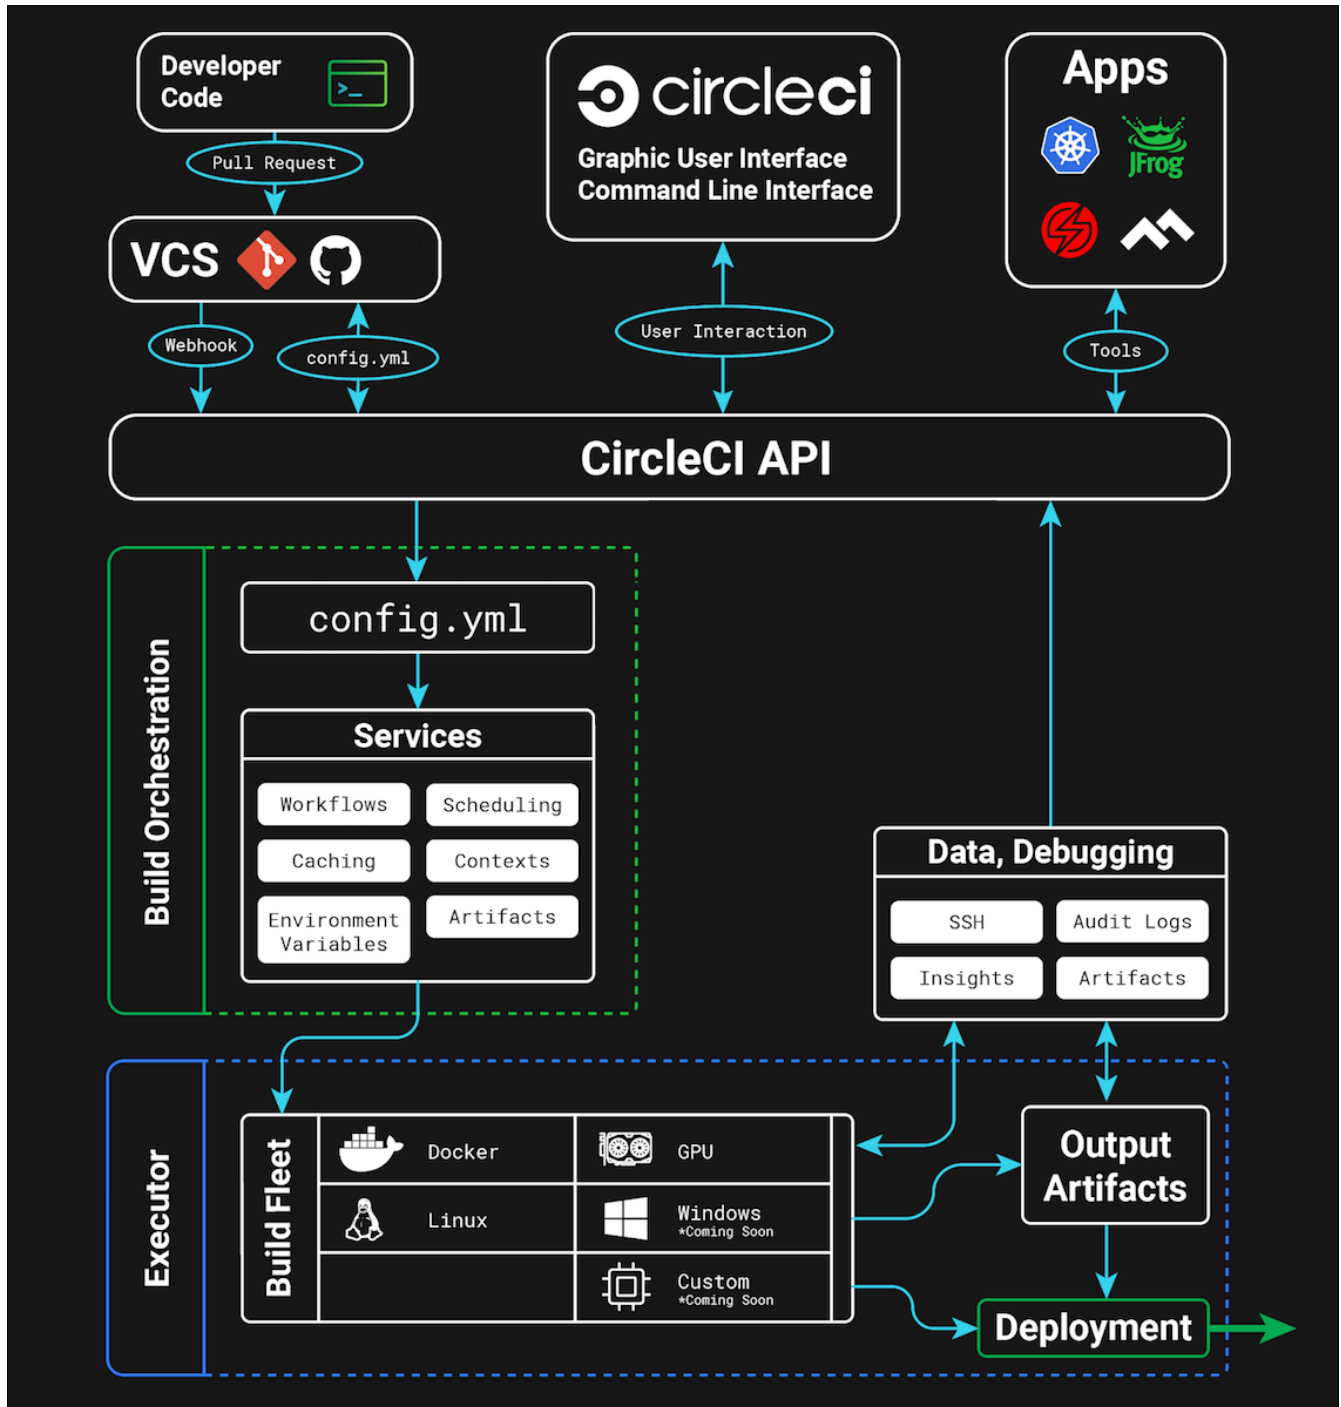

Figure 1. CircleCI Services Architecture

# Build Environments

CircleCI 2.0 uses Nomad as the primary job scheduler. Refer to the [Introduction to Nomad Cluster Operation](#) to learn more about the job scheduler and how to perform basic client and cluster operations.

By default, CircleCI 2.0 Nomad clients automatically provision containers according to the image configured for each job in your `.circleci/config.yml` file.

# Architecture

Figure 1.1 illustrates CircleCI core components, build orchestration services, and executors. The CircleCI [API](#) is a full-featured RESTful API that allows you to access all information and trigger all actions in CircleCI.

Within the CircleCI UI is the Insights page, which acts as a dashboard showing the health of all repositories you are following including:

- median build time
- median queue time
- last build time
- success rate
- parallelism.

CircleCI consists of two primary components: Services and Nomad Clients. Any number of Nomad Clients execute your jobs and communicate back to the Services. All components must access GitHub or your hosted instance of GitHub Enterprise on the network, as illustrated in Figure 2.

## Services Machine

The Services machine must not be restarted and may be backed up using VM snapshotting. If you must restart the Services machine, do so only as a last resort, because a restart will result in downtime. Refer to the [Disaster Recovery](#) chapter for instructions.

DNS resolution may point to the IP address of the Services machine. It is also possible to point to a load balancer, for example an ELB in AWS. The following table describes the ports used for traffic on the Service

machine:

Source	Ports	Use
End Users	80, 443, 4434	HTTP/HTTPS Traffic
Administrators	22	SSH
Administrators	8800	Admin Console
Builder Boxes	all traffic, all ports	Internal Communication
GitHub (Enterprise or .com)	80, 443	Incoming Webhooks

## Nomad Clients

Nomad Clients run without storing state, enabling you to increase or decrease the number of containers as needed.

To ensure enough Nomad clients are running to handle all builds, track the queued builds and increase the number of Nomad Client machines as needed to balance the load. For more on tracking metrics see [System Monitoring](#).

Each machine reserves two vCPUs and 4GB of memory for coordinating builds. The remaining processors and memory create the containers. Larger machines are able to run more containers and are limited by the number of available cores after two are reserved for coordination.

The maximum machine size for a Nomad client is 128GB RAM/ 64 CPUs, contact your CircleCI account representative to request use of larger machines for Nomad Clients.

The following table describes the ports used on Nomad clients:

Source	Ports	Use
End Users	64535-65535	SSH into builds
Administrators	80 or 443	CCI API Access
Administrators	22	SSH
Services Machine	all traffic, all ports	Internal Comms
Nomad Clients (including itself)	all traffic, all ports	Internal Comms

## GitHub

CircleCI uses GitHub or GitHub Enterprise credentials for authentication which, in turn, may use LDAP, SAML, or SSH for access. This means CircleCI will inherit the authentication supported by your central SSO infrastructure.

CircleCI does not support changing the URL or backend Github instance after it has been set up. The following table describes the ports used on machines running GitHub to communicate with the Services and Nomad Client instances.

Source	Ports	Use
Services	22	Git Access
Services	80, 443	API Access
Nomad Client	22	Git Access
Nomad Client	80, 443	API Access

# Introduction to Nomad Cluster Operation

This section provides conceptual and procedural information for operating, backing up, monitoring, and configuring a CircleCI server installation.

```
// You can edit this code!  
// Click here and start typing.  
package main  
  
import "fmt"  
  
func main() {  
    fmt.Println("Hello,  ")  
}
```

# Basic Terminology and Architecture

CircleCI 2.0 uses [Nomad](#) as the primary job scheduler. This chapter provides a basic introduction to Nomad for understanding how to operate the Nomad Cluster in your CircleCI 2.0 installation.

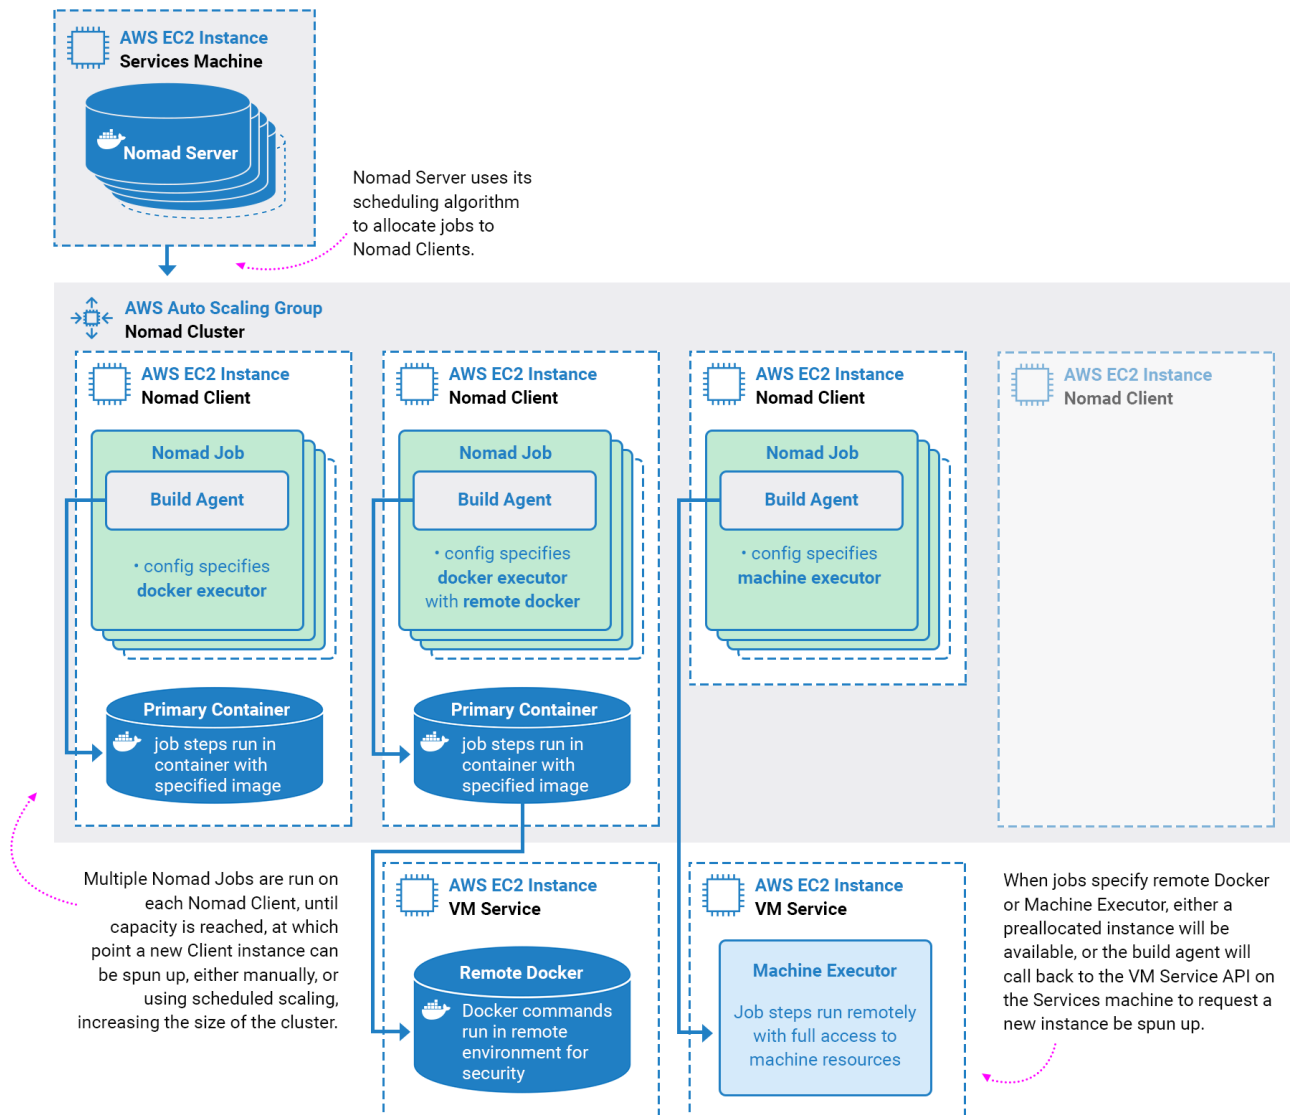

Figure 2. Nomad Cluster Management

- **Nomad Server:** Nomad servers are the brains of the cluster; they receive and allocate jobs to Nomad clients. In CircleCI, a Nomad server runs on your Services machine as a Docker Container.
- **Nomad Client:** Nomad clients execute the jobs they are allocated by Nomad servers. Usually a Nomad client runs on a dedicated machine (often a VM) in order to fully take the advantage of machine power. You can have multiple Nomad clients to form a cluster and the Nomad server allocates jobs to the cluster with its scheduling algorithm.
- **Nomad Jobs:** A Nomad job is a specification, provided by a user, that declares a workload for Nomad. In CircleCI 2.0, a Nomad job corresponds to an execution of a CircleCI job. If the job uses parallelism, say 10 parallelism, then Nomad will run 10 jobs.
- **Build Agent:** Build Agent is a Go program written by CircleCI that executes steps in a job and reports the

results. Build Agent is executed as the main process inside a Nomad Job.

# Basic Operations

The following section is a basic guide to operating a Nomad cluster in your installation.

The **nomad** CLI is installed in the Service instance. It is pre-configured to talk to the Nomad cluster, so it is possible to use the **nomad** command to run the following commands in this section.

## Checking the Jobs Status

To get a list of statuses for all jobs in your cluster, run:

```
nomad status
```

The **Status** is the most important field in the output, with the following status type definitions:

- **running**: Nomad has started executing the job. This typically means your job in CircleCI is started.
- **pending**: There are not enough resources available to execute the job inside the cluster.
- **dead**: Nomad has finished executing the job. The status becomes **dead** regardless of whether the corresponding CircleCI job/build succeeds or fails.

## Checking the Cluster Status

To get a list of your Nomad clients, run:

```
nomad node-status
```

**nomad node-status** reports both Nomad clients that are currently serving (status **active**) and Nomad clients that were taken out of the cluster (status **down**). Therefore, you need to count the number of **active** Nomad clients to know the current capacity of your cluster.

To get more information about a specific client, run the following from that client:

```
nomad node-status -self
```

This will give information such as how many jobs are running on the client and the resource utilization of the client.

## Checking Logs

As noted in the Nomad Jobs section above, a Nomad Job corresponds to an execution of a CircleCI job. Therefore, checking logs of Nomad Jobs sometimes helps you to understand the status of a CircleCI job if

there is a problem. To get logs for a specific job, run:

```
nomad logs -job -stderr <nomad-job-id>
```

Be sure to specify the `-stderr` flag as this is where most Build Agent logs appear.

While the `nomad logs -job` command is useful, the command is not always accurate because the `-job` flag uses a random allocation of the specified job. The term `allocation` is a smaller unit in Nomad Job, which is out of scope for this document. To learn more, please see [the official document](#).

Complete the following steps to get logs from the allocation of the specified job:

1. Get the job ID with `nomad status` command.
2. Get the allocation ID of the job with `nomad status <job-id>` command.
3. Get the logs from the allocation with `nomad logs -stderr <allocation-id>`

## Scaling Up the Client Cluster

Refer to the [\[Scaling\]](#) section of the Configuration chapter for details about adding Nomad Client instances to an AWS auto scaling group and using a scaling policy to scale up automatically according to your requirements.

## Shutting Down a Nomad Client

When you want to shutdown a Nomad client, you must first set the client to `drain` mode. In `drain` mode, the client will finish any jobs that have already been allocated but will not be allocated any new jobs.

1. To drain a client, log in to the client and set the client to drain mode with `node-drain` command as follows:

```
nomad node-drain -self -enable
```

2. Then, make sure the client is in drain mode using the `node-status` command:

```
nomad node-status -self
```

Alternatively, you can drain a remote node with `nomad node-drain -enable -yes <node-id>`.

## Scaling Down the Client Cluster

To set up a mechanism for clients to shutdown, first entering `drain` mode, then waiting for all jobs to be finished before terminating the client, you can configure an [ASG Lifecycle Hook](#) that triggers a script for

scaling down instances.

The script should use the commands in the section above to do the following:

1. Put the instance in drain mode
2. Monitor running jobs on the instance and wait for them to finish
3. Terminate the instance = Monitoring Your Installation :page-layout: classic-docs :page-liquid: :icons: font :toc: macro :toc-title:

This section includes information on gathering metrics for monitoring your CircleCI installation and scaling your Nomad cluster to meet your needs.

# System Monitoring

To enable system and Docker metrics forwarding to either AWS Cloudwatch or Datadog, navigate to your CircleCI Management Console, select Settings from the menu bar and scroll down to enable the provider of your choice. To get straight to this section use the following URL, substituting in your CircleCI URL:

```
https://<your-circleci-hostname>.com:8800/settings#cloudwatch_metrics
```

## VM Service and Docker Metrics

VM Host and Docker services metrics are forwarded via [Telegraf](#), a plugin-driven server agent for collecting and reporting metrics.

Following are the enabled metrics:

- [CPU](#)
- [Disk](#)
- [Memory](#)
- [Networking](#)
- [Docker](#)

## Nomad Job Metrics

[Nomad job metrics](#) are enabled and emitted by the Nomad Server agent. Five types of metrics are reported:

Metric	Description
<code>circle.nomad.server_agent.poll_failure</code>	Returns 1 if the last poll of the Nomad agent failed, otherwise it returns 0.
<code>circle.nomad.server_agent.jobs.pending</code>	Returns the total number of pending jobs across the cluster.
<code>circle.nomad.server_agent.jobs.running</code>	Returns the total number of running jobs across the cluster.
<code>circle.nomad.server_agent.jobs.complete</code>	Returns the total number of complete jobs across the cluster.
<code>circle.nomad.server_agent.jobs.dead</code>	Returns the total number of dead jobs across the cluster.

When the Nomad metrics container is running normally, no output will be written to standard output or standard error. Failures will elicit a message to standard error.

# Supported Platforms

We have two built-in platforms for metrics and monitoring: AWS CloudWatch and DataDog. The sections below detail enabling and configuring each in turn.

## AWS CloudWatch

To enable AWS CloudWatch complete the following:

1. Navigate to the settings page within your Management Console. You can use the following URL, substituting your CircleCI URL:

```
`https://<your-circleci-  
hostname>.com:8800/settings#cloudwatch_metrics`
```

2. Check Enabled under AWS CloudWatch Metrics to begin configuration.

```
![AWS CloudWatch](images/metrics_aws_cloudwatch1.png){ width=400px }
```

## AWS CloudWatch Configuration

There are two options for configuration:

- Use the IAM Instance Profile of the services box and configure your custom region and namespace.

```
![Configuration IAM](images/metrics_aws_cloudwatch2a.png){  
width=400px }
```

- Alternatively, you may use your AWS Access Key and Secret Key along with your custom region and namespace.

```
![Configuration Alt](images/metrics_aws_cloudwatch2b.png){  
width=400px }
```

After saving you can **verify** that metrics are forwarding by going to your AWS CloudWatch console.

\pagebreak

## DataDog

To enable Datadog complete the following:

1. Navigate to the settings page within your Management Console. You can use the following URL, substituting your CircleCI URL:

```
`https://<your-circleci-hostname>.com:8800/settings#datadog_metrics`
```

2. Check Enabled under Datadog Metrics to begin configuration

```
![Enable DataDog](images/metrics_datadog1.png){ width=400px }
```

3. Enter your DataDog API Key

```
![DataDog API Key](images/metrics_datadog2.png){ width=400px }
```

After saving you can **verify** that metrics are forwarding by going to the DataDog metrics summary.

# Custom Metrics

Custom Metrics using a Telegraf configuration file may be configured in addition to the predefined CloudWatch and Datadog metrics described above. Telegraf can also be used instead of CloudWatch and Datadog for more fine grained control.

## Custom Metrics

Enable forwarding to custom Telegraf output providers

Files matching `/etc/circleconfig/telegraf/*.conf` on this host will be included with the telegraf configuration. This allows you to specify custom output providers. For more information visit <https://circleci.com/docs/2.0/monitoring/>.

Example

```
# Put this in /etc/circleconfig/telegraf/kafka.conf, then restart the telegraf container
[[outputs.kafka]]
  brokers = ["example.com:9092"]
  topic = "circleci"
```

## Configuring Custom Metrics

Configuration options are based on Telegraf's documented output plugins. See their documentation [here](#).

For example, if you would like to use the InfluxDB Output Plugin you would need to follow these steps:

1. SSH into the Services Machine
2. `cd /etc/circleconfig/telegraf/influxdb.conf`
3. Adding the desired outputs, for example:

```
[[output.influxdb]]
  url = "http://52.67.66.155:8086"
  database = "testdb"
```

4. Run `docker restart telegraf` to restart the container to load or reload any changes.

You may check the logs by running `docker logs -f telegraf` to confirm your output provider (e.g. influx) is listed in the configured outputs.

Additionally, if you would like to ensure that all metrics in an installation are tagged against an environment you could place the following code in your config:

```
[global_tags]
Env="<staging-circleci>"
```

Please see the InfluxDB [documentation](<https://github.com/influxdata/influxdb#installation>) for default and advanced installation steps.

Note: Any changes to the config will require a restart of the system. <!--what system? the whole CircleCI system? incurring downtime?-->

```
\label{sec:scaling}
```

# Scheduled Scaling

By default, an Auto Scaling Group (ASG) is created on your AWS account for your Nomad cluster. Go to your EC2 Dashboard and select Auto Scaling Groups from the left side menu. Then, in the Instances tab, set the Desired and Minimum number to define the number Nomad Clients to spin up and keep available. Use the Scaling Policy tab of the Auto Scaling page to scale up your group automatically only at certain times, see below for best practices for defining policies.

Refer to our guide to [shutting down a nomad client](#) for instructions on draining and scaling down the Nomad Clients.

## Auto Scaling Policy Best Practices

There is a [blog post series](https://circleci.com/blog/mathematical-justification-for-not-letting-builds-queue/) where CircleCI engineering spent time running simulations of cost savings for the purpose of developing a general set of best practices for Auto Scaling. Consider the following best practices when setting up AWS Auto Scaling:

1. In general, size your cluster large enough to avoid queueing builds. That is, less than one second of queuing for most workloads and less than 10 seconds for workloads run on expensive hardware or at highest parallelism. Sizing to reduce queuing to zero is best practice because of the high cost of developer time. It is difficult to create a model in which developer time is cheap enough for under-provisioning to be cost-effective.
2. Create an Auto Scaling Group with a Step Scaling policy that scales up during the normal working hours of the majority of developers and scales back down at night. Scaling up during the weekday normal working hours and back down at night is the best practice to keep queue times down during peak development, without over provisioning at night when traffic is low. Looking at millions of builds over time, a bell curve during normal working hour emerges for most data sets.

This is in contrast to auto scaling throughout the day based on traffic fluctuations, because modelling revealed that boot times are actually too long to prevent queuing in real time. Use [\[Amazon's Step Policy\]](http://docs.aws.amazon.com/autoscaling/latest/userguide/as-scaling-simple-step.html) instructions to set this up along with Cloudwatch Alarms. = Setting Up HTTP Proxies :page-layout: classic-docs :page-liquid: :icons: font :toc: macro :toc-title:

This section describes how to configure CircleCI to use an HTTP proxy.

# Overview

If you are setting up your proxy through Amazon, read this before proceeding:

[Using an HTTP Proxy - AWS Command Line Interface](#)

Avoid proxying internal requests, especially for the Services machine. To add these to the **NO\_PROXY** rules, run:

```
export NO_PROXY=<services_box_ip>
```

In an ideal case, traffic to S3 will not be proxied, and will instead be bypassed by adding **s3.amazonaws.com**, **\*.s3.amazonaws.com** to the **NO\_PROXY** rule.

These instructions assume an unauthenticated HTTP proxy at **10.0.0.33:3128**, a Services machine at **10.0.1.238** and use of **ghe.example.com** as the GitHub Enterprise host.

The following proxy instructions must be completed **before** installing CircleCI on fresh VMs or instances. You must also configure JVM OPTs again as well as described below.

# Service Machine Proxy Configuration

The Service machine has many components that need to make network calls, as follows:

- **External Network Calls** - Replicated is a vendor service that we use for the Management Console of CircleCI. CircleCI requires Replicated to make an outside call to validate the license, check for updates, and download upgrades. Replicated also downloads docker, installs it on the local machine, and uses a Docker container to create and configure S3 buckets. GitHub Enterprise may or may not be behind the proxy, but github.com will need to go through the proxy.
- **Internal Network Calls**
  - If S3 traffic requires going through an HTTP proxy, CircleCI must pass proxy settings into the container.
  - The CircleCI instance on the Services machine runs in a Docker container, so it must to pass the proxy settings to the container to maintain full functionality.

## Set up Service Machine Proxy Support

For a static installation not on AWS, SSH into the Services machine and run the following code snippet with your proxy address:

```
echo '{"HttpProxy": "http://<proxy-ip:port>"}' |
sudo tee /etc/replicated.conf
(cat <<'EOF'
HTTP_PROXY=<proxy-ip:port>
HTTPS_PROXY=<proxy-ip:port>

EOF
| sudo tee -a /etc/circle-installation-customizations
sudo service replicated-ui stop; sudo service replicated stop;
sudo service replicated-operator stop; sudo service replicated-ui
start;
sudo service replicated-operator start; sudo service replicated start
```

If you run in Amazon's EC2 service then you'll need to include **169.254.169.254** EC2 services as shown below:

```

echo '{"HttpProxy": "http://<proxy-ip:port>"}' |
sudo tee /etc/replicated.conf
(cat <<'EOF'
HTTP_PROXY=<proxy-ip:port>
HTTPS_PROXY=<proxy-ip:port>
NO_PROXY=169.254.169.254,<circleci-service-ip>,
127.0.0.1,localhost,ghe.example.com
JVM_OPTS="-Dhttp.proxyHost=<ip> -Dhttp.proxyPort=<port>
-Dhttps.proxyHost=<proxy-ip> -Dhttps.proxyPort=<port>
-Dhttp.nonProxyHosts=169.254.169.254|<circleci-service-ip>|
127.0.0.1|localhost|ghe.example.com"

EOF
| sudo tee -a /etc/circle-installation-customizations
sudo service replicated-ui stop; sudo service replicated stop;
sudo service replicated-operator stop; sudo service replicated-ui
start;
sudo service replicated-operator start; sudo service replicated start

```

The above is not handled by by our enterprise-setup script and will need to be added to the user data for the Services machine startup or done manually.

## Corporate Proxies

Also note that when the instructions ask you if you use a proxy, they will also prompt you for the address. It is **very important** that you input the proxy in the following format **<protocol>://<ip>:<port>**. If you are missing any part of that, then **apt-get** won't work correctly and the packages won't download.

## Nomad Client Configuration

### External Network Calls

CircleCI uses **curl** and **awscli** scripts to download initialization scripts, along with jars from Amazon S3. Both **curl** and **awscli** respect environment settings, but if you have whitelisted traffic from Amazon S3 you should not have any problems.

### Internal Network Calls

- CircleCI JVM:
- Any connections to other Nomad Clients or the Services machine should be excluded from HTTP proxy
- Connections to GitHub Enterprise should be excluded from HTTP proxy

- The following contains parts that may be impacted due to a proxy configuration:
- [Amazon EC2 metadata](#). This **should not** be proxied. If it is, then the machine will be misconfigured.
- Amazon S3 traffic — note S3 discussion above
- Amazon EC2 API - EC2 API traffic may need to be proxied. You would note lots of failures (timeout failures) in logs if the proxy setting is misconfigured, but it will not block CircleCI from functioning.

## Nomad Client Proxy Setup

- If you are installing CircleCI Server on AWS using Terraform, you should add the below to your Nomad client launch configuration – these instructions should be added to `/etc/environment`.
- If you are running a static installation, add to the server before installation.

```
#!/bin/bash

(cat << 'EOF'
HTTP_PROXY=<proxy-ip:port>
HTTPS_PROXY=<proxy-ip:port>
NO_PROXY=169.254.169.254,<circleci-service-ip>,
127.0.0.1,localhost,ghe.example.com
JVM_OPTS="-Dhttp.proxyHost=<ip> -Dhttp.proxyPort=<port>
-Dhttps.proxyHost=<proxy-ip> -Dhttps.proxyPort=3128
-Dhttp.nonProxyHosts=169.254.169.254|<circleci-service-ip>|
127.0.0.1|localhost|ghe.example.com"
EOF
) | sudo tee -a /etc/environment

set -a
. /etc/environment
```

You will also need to follow [these instructions](#) to make sure your containers have outbound/proxy access.

## Troubleshooting

If you cannot access the CircleCI Management Console, but the Services machine seems to be running, try to SSH tunnel into the machine by running the following, substituting your proxy address and the IP address of your Services machine:

```
ssh -L 8800:<address you want to proxy through>:8800
ubuntu@<ip_of_services_machine>
```

# Data Persistence

Contact [support@circleci.com](mailto:support@circleci.com) to discuss externalizing services for data persistence.

# Authentication

This document describes how to enable, configure, and test CircleCI to authenticate users with OpenLDAP or Active Directory credentials.

LDAP is not supported with existing installations, only clean installations may use LDAP.

# Prerequisites

- Install and configure your LDAP server and Active Directory.
- GitHub Enterprise must be configured and is the source of organizations and projects to which users have access.
- Install a new instance of CircleCI 2.0 with no existing users, following our [\[install\]](#) guide.
- Contact [CircleCI support](#) and file a feature request for CircleCI Server.

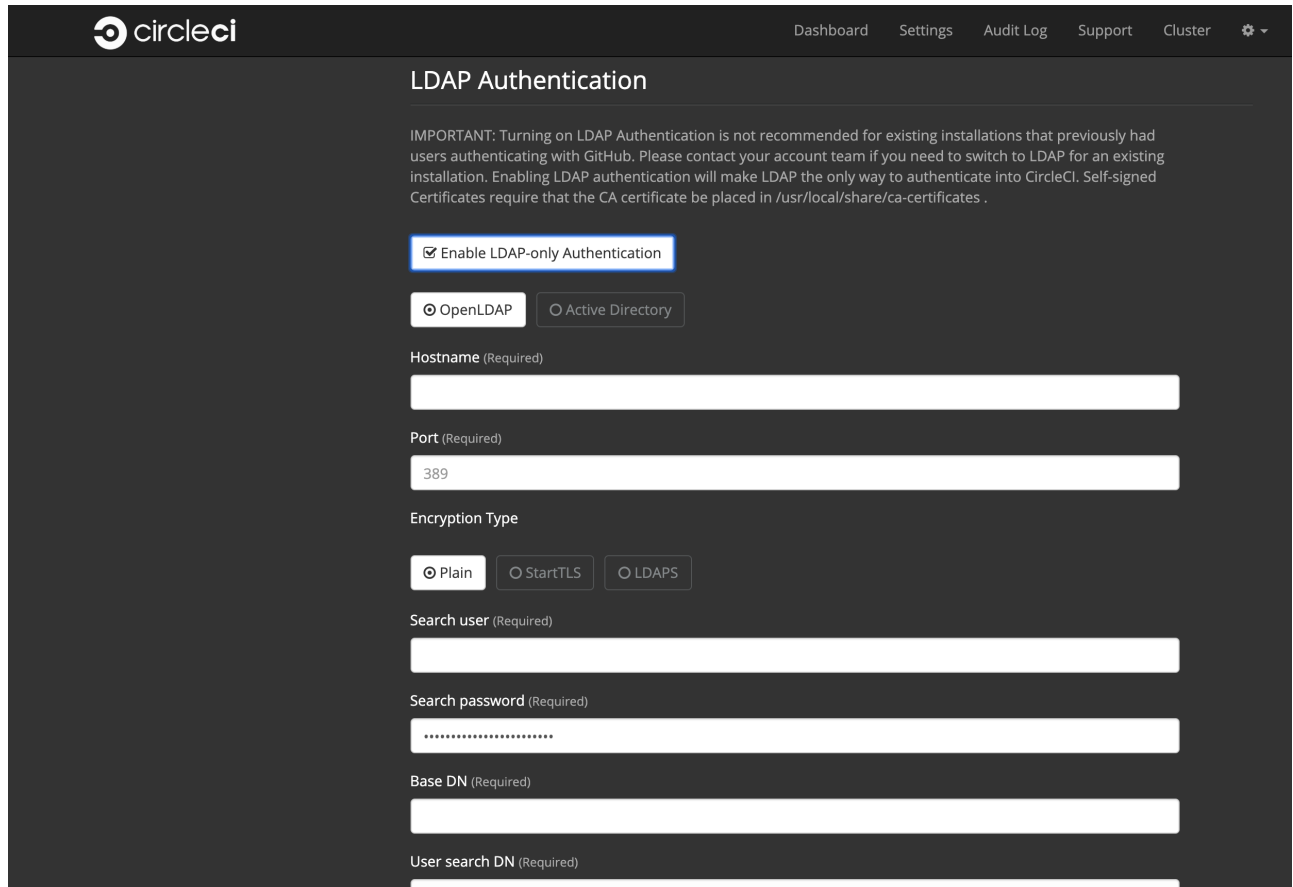

After completing this configuration, all users must log in to CircleCI with their LDAP credentials. After logging in to CircleCI, each user will then click the Connect button on the Accounts page to connect and authenticate their GitHub account.

# Configure LDAP Authentication

This section provides the steps to configure LDAP in the CircleCI Server Management Console:

1. Verify access over the LDAP/AD ports to your LDAP/AD servers.
2. Log in as administrator to the Management Console for your newly installed CircleCI 2.0 instance.
3. Navigate to the Settings page and check the Enable LDAP-only Authentication button. Select either OpenLDAP or Active Directory.

The screenshot shows the 'LDAP Authentication' configuration page in the CircleCI management console. The page has a dark theme with a navigation bar at the top containing 'Dashboard', 'Settings', 'Audit Log', 'Support', and 'Cluster'. The main heading is 'LDAP Authentication'. Below the heading is an important note: 'IMPORTANT: Turning on LDAP Authentication is not recommended for existing installations that previously had users authenticating with GitHub. Please contact your account team if you need to switch to LDAP for an existing installation. Enabling LDAP authentication will make LDAP the only way to authenticate into CircleCI. Self-signed Certificates require that the CA certificate be placed in /usr/local/share/ca-certificates.' The configuration options include: a checkbox for 'Enable LDAP-only Authentication' (checked), radio buttons for 'OpenLDAP' (selected) and 'Active Directory', a 'Hostname (Required)' text field, a 'Port (Required)' text field with '389' entered, 'Encryption Type' radio buttons for 'Plain' (selected), 'StartTLS', and 'LDAPS', a 'Search user (Required)' text field, a 'Search password (Required)' text field with masked characters, a 'Base DN (Required)' text field, and a 'User search DN (Required)' text field.

4. Fill in your LDAP instance Hostname and port number.
5. Select the encryption type (plain text is not recommended).
6. Fill in the Search user field with the LDAP admin username using the format `cn=<admin>,dc=<example>,dc=<org>` replacing `admin`, `example`, and `org` with appropriate values for your datacenter.
7. Fill in the Search password field with the LDAP admin password.
8. Fill in the User search DN field with an appropriate value using the format `ou=<users>` replacing `users` with the value used in your LDAP instance.
9. Fill in the Username field with an appropriate unique identifier used for your users, for example, `mail`.
10. Fill in the Group Membership field with an appropriate value. By default, the value is `uniqueMember` for OpenLDAP and `member` for Active Directory. This field will list member `dn` for a group.

11. Fill in the Group Object Class field with an appropriate value. By default, the value is `groupOfUniqueNames` for OpenLDAP and `group` for Active Directory. The value of the `objectClass` field indicates a `dn` is a group.
12. (Optional) Fill in the Test username and Test password fields with a test email and password for an LDAP user you want to test.
13. Save the settings.

A user who logs in will be redirected to the Accounts page of the CircleCI application with a Connect button that they must use to connect their GitHub account. After they click Connect, an LDAP section with their user information (for example, their email) on the page will appear and they will be directed to authenticate their GitHub account. After authenticating their GitHub account users are directed to the **Job page** to use CircleCI.

A user who has authenticated with LDAP and is then removed from LDAP/AD will be able to access CircleCI as long as they stay logged in (because of cookies). As soon as the user logs out or the cookie expires, they will not be able to log back in. A user's ability to see projects or to run builds is defined by their GitHub permissions. Therefore, if GitHub permissions are synced with LDAP/AD permissions, a removed LDAP/AD user will automatically lose authorization to view or access CircleCI as well.

# Troubleshooting

Troubleshoot LDAP server settings with LDAP search as follows:

```
ldapsearch -x LLL -h <ldap_address_server> = VM Service :page-layout: classic-docs :page-liquid: :icons: font :toc: macro :toc-title:
```

This section outlines how to set up VM service for your CircleCI installation for **machine** executor and remote Docker jobs, as well as how to customize your own VM service images.

This configuration is only available for installations on AWS, please contact your CircleCI account representative to request this configuration for a static installation.

# Overview

VM service enables users of CircleCI Server, installed on AWS, to run jobs using the [Remote Docker Environment](#) and the [machine executor](#).

## Configuration

## VM Provider

Configure automated provisioning of Virtual Machines to enable users to use Remote Docker or the **machine** executor.

☐ None

☒ AWS EC2

☐ On-Host

We use your EC2 credentials to automatically provision boxes on demand when users request Remote Docker or the **machine** executor.

**AWS Region** (Required)

**EC2 Subnet ID** (Required)

AWS EC2 Subnet ID to be used for VM creation. Should be in the region specified above.

**EC2 Security Group ID** (Required)

AWS EC2 Security Group ID to be assigned for all VMs. Should be in the region specified above.

**Custom VM AMI**

AMI to be used for machine executor and remote docker VMs instead of default. Should be in the selected region and available for AWS User specified above.

**AWS Instance Type** (Required)

Instance type the VM services should use.

**AWS Authentication**

☒ IAM Instance Profile

☐ IAM User (Key+Secret)

**VM Preallocation**

Number of VMs to preallocate and have waiting to execute jobs. Set to 0 to have only on-demand VM provisioning.

**Remote Docker**

**Machine Executor**

To configure VM service, it is best practice to select the AWS EC2 option in the Management Console Settings, which will allow CircleCI to run remote Docker and `machine` executor jobs using dedicated EC2 instances.

If you do not provide a custom [Amazon Machine Image](#) (AMI) for VM service, `machine` executor and remote Docker jobs on CircleCI Server will run using the same machine image that we provide by default on Cloud: an Ubuntu 14.04 or 16.04 image with Docker version `17.03.0-ce` and docker-compose version `1.9.0`, along with a selection of common languages, tools, and frameworks. See the [picard-vm-image branch of our image-builder repository](#) for details.

## Customization

It may be beneficial to customize the VM service image for your installation of CircleCI. This will allow you to specify other versions of Docker and Docker Compose, as well as install any additional dependencies that may be part of your CI/CD pipeline. Without doing so, you will likely need to run these additional install and update steps on every commit as part of your `config.yml` file.

To build custom VM service images:

1. Clone our image builder repo: <https://github.com/circleci/image-builder/tree/picard-vm-image>
2. Open `aws-vm.json` in your editor and fill in the required groups. An access key and secret key are required to upload. Handle the key and secret process according to your requirements, but consider restricting the `ami_groups` to only within your organization
3. Run `packer build aws-vm.json`

Refer to [https://packer.io/docs/builders/amazon-ebs.html#ami\\_groups](https://packer.io/docs/builders/amazon-ebs.html#ami_groups) for more information and see <https://github.com/circleci/image-builder/blob/picard-vm-image/provision.sh> for details about settings.

You will need to associate the `circleci` user with the image you want to use as shown in [this](#) example.

The following sections summarize the key files and variables that impact CircleCI Server behavior.

### Notable Files & Folders

Need	Path	More info
General Config	<code>/etc/circle-installation-customizations</code>	See table below for values
JVM Heap Sizes	<code>/etc/circleconfig/XXXX/customizations</code> Supports: frontend, test_results	Adjust heap size for individual containers with <code>JVM_HEAP_SIZE</code>
Custom CA Certs	<code>/usr/local/share/ca-certificates/</code>	
Container Customizations	<code>/etc/circleconfig/XXX/customizations</code>	Used lots of places in replicated

Need	Path	More info
<code>/etc/hosts</code>	<code>/etc/hosts</code>	Respected by several containers including frontend, copied to container's <code>/etc/hosts</code>
<code>/etc/environment</code>	<code>/etc/environment</code>	Respected by all containers

## Properties of `/etc/circle-installation-customizations`

Every property should be in the format `export ENV_VAR="value"`

Property	Impact	More info
<code>CIRCLE_URL</code>	Override the scheme and host that CircleCI uses	
<code>JVM_HEAP_SIZE</code>	Set JVM heap size for <b>all</b> containers reading this property	Use container specific settings when possible (see files above)

## Other Properties and Env Vars

Property	Impact	More info
<code>HTTP_PROXY</code> , <code>NO_PROXY</code>	Proxy for replicated and other services outside CircleCI containers to use	

## Job and Instance Management

Jobs run using the remote Docker environment, or the **machine** executor are scheduled and dispatched by Nomad, even though the jobs are not run on Nomad clients. See our [Introduction to Nomad Cluster Operation](#) for more about Nomad commands and terminology.

A cron job is scheduled to cycle all default and preallocated instances at least once per day to ensure instances don't end up in a dead/bad state. = Setting Up Certificates :page-layout: classic-docs :page-liquid: :icons: font :toc: macro :toc-title:

This document provides a script for using a custom Root Certificate Authority and the process for using an Elastic Load Balancing certificate.

# Using a Custom Root CA

Any valid certificates added to the following path will be trusted by CircleCI services:

`usr/local/share/ca-certificates/`

The following example `openssl` command is one way of placing the certificate. It is also possible to pull a certificate from a vault/PKI solution within your company.

Some installation environments use internal Root Certificate Authorities for encrypting and establishing trust between servers. If you are using a customer Root certificate, you will need to import and mark it as a trusted certificate at CircleCI GitHub Enterprise instances. CircleCI will respect such trust when communicating with GitHub and webhook API calls.

CA Certificates must be in a format understood by Java Keystore, and include the entire chain.

The following script provides the necessary steps:

```
GHE_DOMAIN=github.example.com
```

```
# Grab the CA chain from your GitHub Enterprise deployment.
```

```
openssl s_client -connect ${GHE_DOMAIN}:443 -showcerts < /dev/null | sed  
-ne '/-BEGIN CERTIFICATE-/,/-END CERTIFICATE-/p' > /usr/local/share/ca-  
certificates/ghe.crt
```

Then, navigate to the system console at port 8800 and change the protocol to upgraded. You can change the protocol to HTTPS (TLS/SSLEnabled) setting and restart the services. When trying Test GitHub Authentication you should get Success now rather than x509 related error.

# Setting up ELB Certificates

CircleCI requires the following steps to get ELB (Elastic Load Balancing) certificates working as your primary certs. The steps to accomplish this are below. You will need certificates for the ELB and CircleCI Server as described in the following sections.

Opening the port for HTTP requests will allow CircleCI to return a HTTPS redirect.

1. Open the following ports on your ELB:

Load Balancer Protocol	Load Balancer Port	Instance Protocol	Instance Port	Cipher	SSL Certificate
HTTP	80	HTTP	80	N/A	N/A
SSL	443	SSL	443	Change	your-cert
SSL	3000	SSL	3000	Change	your-cert
HTTPS	8800	HTTPS	8800	Change	your-cert
SSL	8081	SSL	8081	Change	your-cert
SSL	8082	SSL	8082	Change	your-cert

2. Add the following security group on your ELB:

The sources below are left open so that anybody can access the instance over these port ranges. If that is not what you want, then feel free to restrict them. Users will experience reduced functionality if your stakeholders are using IP addresses outside of the Source Range.

Type	Protocol	Port Range	Source
SSH	TCP	22	0.0.0.0
HTTPS	TCP	443	0.0.0.0
Custom TCP Rule	TCP	8800	0.0.0.0
Custom TCP Rule	TCP	64535-65535	0.0.0.0

3. Next, in the management console for CircleCI, upload a valid certificate and key file to the **Privacy** Section. These don't need to be externally signed or even current certs as the actual cert management is done at the ELB. But, to use HTTPS requests, CircleCI requires a certificate and key in which the "Common Name (FQDN)" matches the hostname configured in the admin console.
4. It is now possible to set your Github Authorization Callback to **https** rather than **http**.

## Using Self-Signed Certificates

Because the ELB does not require a *current* certificate, you may choose to generate a self-signed certificate

with an arbitrary duration.

1. Generate the certificate and key using openssl command `openssl req -newkey rsa:2048 -nodes -keyout key.pem -x509 -days 1 -out certificate.pem`
2. Provide the appropriate information to the prompts.

The Common Name provided must match the host configured in CircleCI.

3. Save the certificate.pem and key.pem file locally.

# Setting up TLS/HTTPS on CircleCI Server

You may use various solutions to generate valid SSL certificate and key file. Two solutions are provided below.

## Using Certbot

This section describes setting up TLS/HTTPS on your Server install using Certbot by manually adding a DNS record set to the Services machine. Certbot generally relies on verifying the DNS record via either port 80 or 443, however this is not supported on CircleCI Server installations as of 2.2.0 because of port conflicts.

1. Stop the Service CircleCI Server Management Console (<http://<circleci-hostname>.com:8800>).
2. SSH into the Services machine.
3. Install Certbot and generate certificates using the following commands:

```
sudo apt-get update
sudo apt-get install software-properties-common
sudo add-apt-repository ppa:certbot/certbot
sudo apt-get update
sudo apt-get install certbot
certbot certonly --manual --preferred-challenges dns
```

4. You will be instructed to add a DNS TXT record.
5. After the record is successfully generated, save `fullchain.pem` and `privkey.pem` locally.

If you are using Route 53 for your DNS records, adding a TXT record is straightforward. When you're creating a new record set, be sure to select type `TXT` and provide the appropriate value enclosed in quotes.

## Adding the certificate to CircleCI Server

Once you have a valid certificate and key file in `.pem` format, you must upload it to CircleCI Server.

1. To do so, navigate to `hostname:8800/console/settings`
2. Under "Privacy" section, check the box for "SSL only (Recommended)"
3. Upload your newly generated certificate and key
4. Click "Verify TLS Settings" to ensure everything is working
5. Click "Save" at the bottom of the settings page and restart when prompted

More information is available [here](#).

Ensure the hostname is properly configured from the Management Console (<http://<circleci-hostname>.com:8800>) and that the hostname used matches the DNS records associated with the TLS certificates.

Make sure the Auth Callback URL in Github/Github Enterprise matches the domain name pointing to the Services machine, including the protocol used, for example **https://info-tech.io/**. = Managing User Accounts :page-layout: classic-docs :page-liquid: :icons: font :source-highlighter: pygments.rb :toc: macro :toc-title:

This section provides information to help system administrators manage accounts for their users. For an overview of user accounts, view the Admin settings overview from the CircleCI app by clicking on your profile in the top right corner and selecting Admin. This overview provides the active user count and the total number of licensed users.

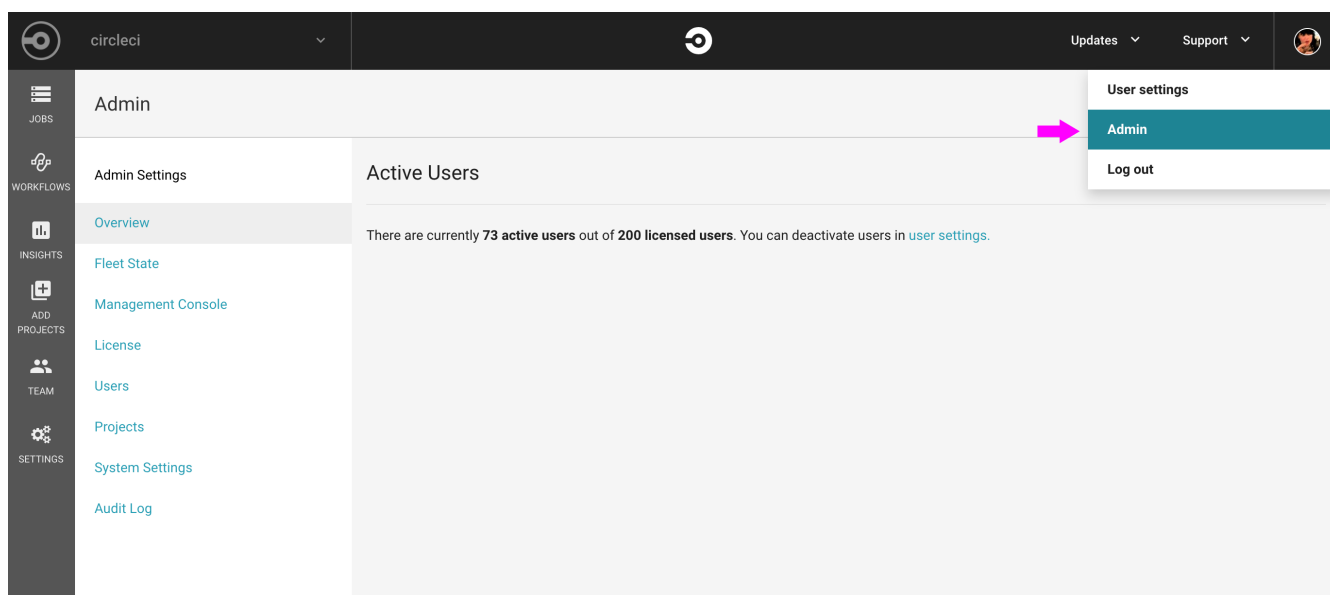

Figure 3. Admin Settings – Account Overview

# Suspending Accounts

When an account is no longer required, you can suspend the account so it will no longer be active and will not count against your license quota. To suspend an account:

1. Navigate to your CircleCI Admin Settings
2. Select Users from the Admin Settings menu
3. Scroll to locate the account in either the Active or Inactive window
4. Click **Suspend** next to the account name and the account will appear in the Suspended window

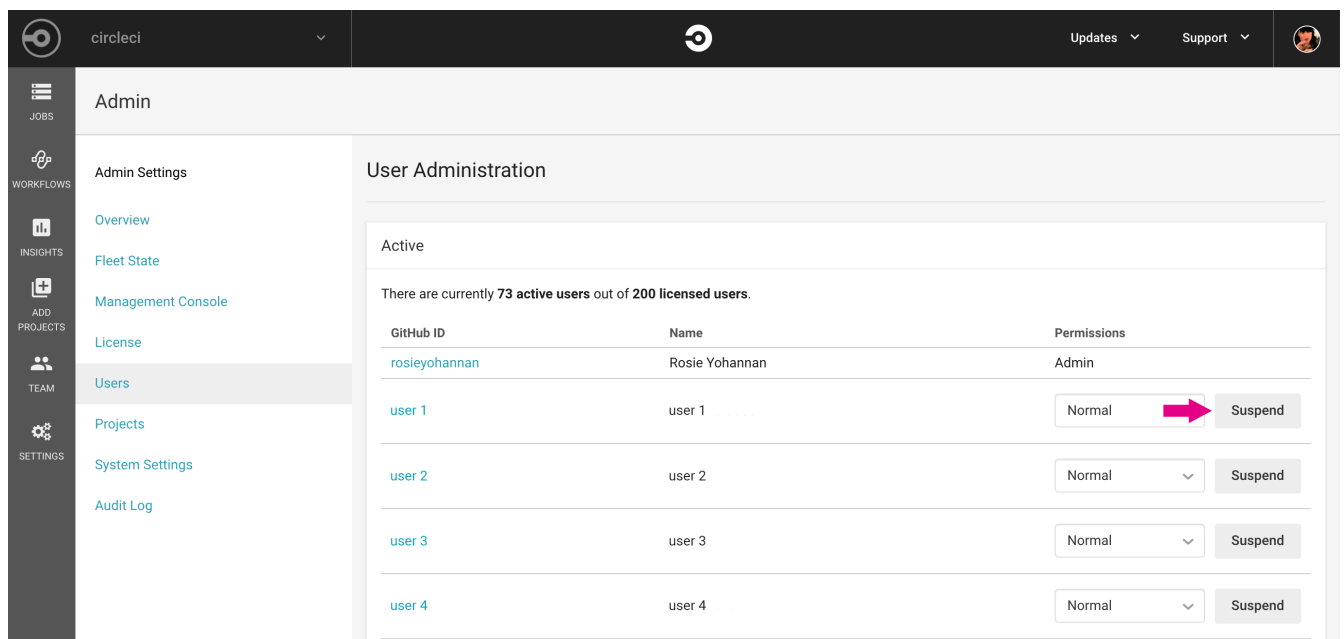

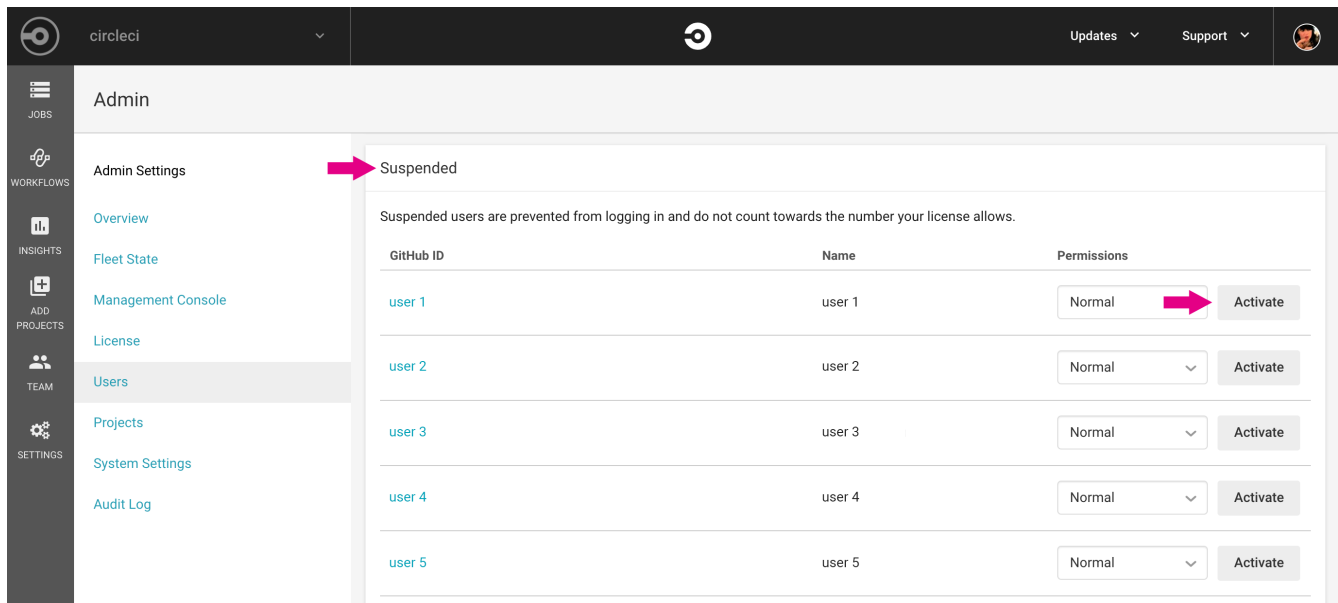

Figure 4. Suspending an Account

# Reactivating a Suspended User Account

To reactivate an account that has been suspended:

1. Navigate to your CircleCI Admin Settings
2. Select Users from the Admin Settings menu
3. View the Suspended window
4. Click on **Activate** next to the User you wish to grant access and the account will appear in the Active window

The screenshot shows the CircleCI Admin interface. The left sidebar contains the following menu items: JOBS, WORKFLOWS, INSIGHTS, ADD PROJECTS, TEAM, and SETTINGS. The 'Admin' section is expanded, showing 'Admin Settings', 'Overview', 'Fleet State', 'Management Console', 'License', 'Users' (highlighted), 'Projects', 'System Settings', and 'Audit Log'. The 'Suspended' window is open, displaying a table of suspended users. A pink arrow points from 'Admin Settings' to the 'Suspended' tab. Another pink arrow points to the 'Activate' button for 'user 1'.

GitHub ID	Name	Permissions	
user 1	user 1	Normal	Activate
user 2	user 2	Normal	Activate
user 3	user 3	Normal	Activate
user 4	user 4	Normal	Activate
user 5	user 5	Normal	Activate

Figure 5. Reactivate Existing Users

# Controlling Account Access

Any user associated with your GitHub.com or Github Enterprise organization can create a user account for your CircleCI installation. In order to control who has access, you can automatically suspend **all** new users, requiring an administrator to activate them before they can log in. To access this feature:

1. Navigate to your CircleCI Admin Settings
2. Select System Settings from the Admin Settings menu
3. Set Suspend New Users to **True**

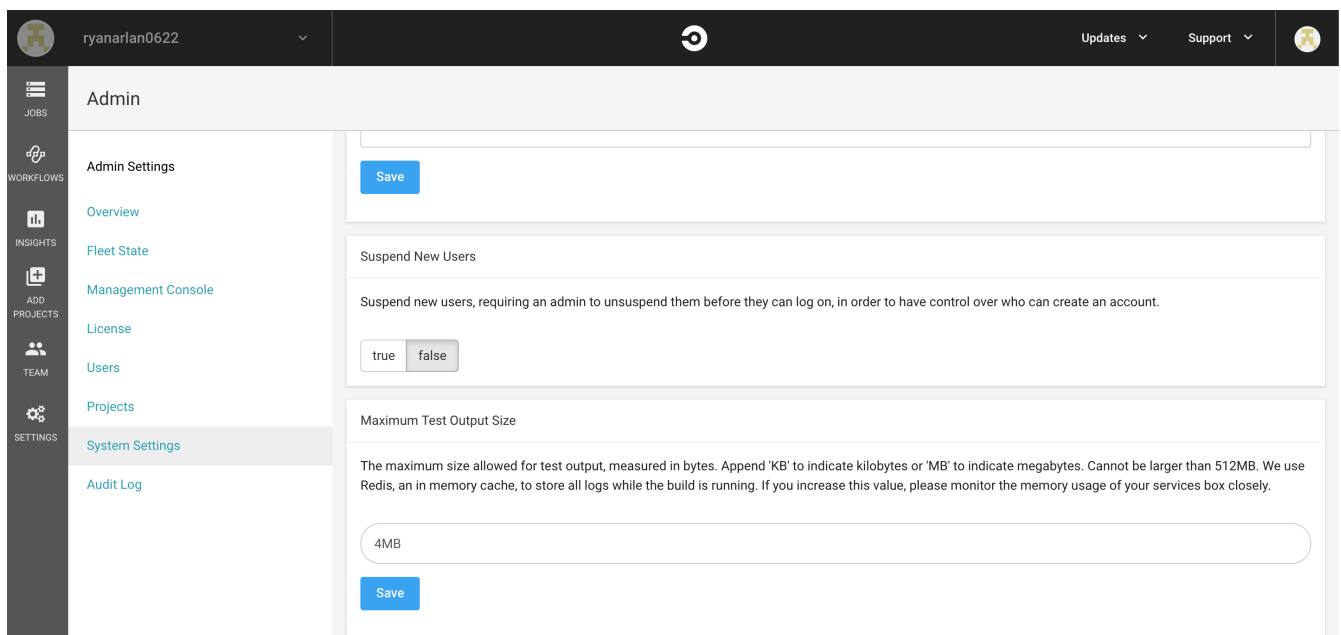

Figure 6. Auto Suspend New Users

## Activating a Suspended New User Account

To activate an **new** account that was automatically suspended, and allow the associated user access to your installation of CircleCI Server:

1. Navigate to your CircleCI Admin Settings
2. Select Users from the Admin Settings menu
3. View the Suspended New Users window
4. Click on **Activate** next to the User you wish to grant access and the account will appear in the Active window

Figure 7. Activate a Suspended New User

## Limit User Registrations by Github Organization

When using Github.com, you can limit who can register with your CircleCI install to people with **some** connection to your approved organizations list. To access this feature:

1. Navigate to your CircleCI Admin Settings page
2. Select System Settings from the Admin Setting menu
3. Scroll down to Required Org Membership List
4. Enter the organization(s) you wish to approve. If entering more than one organization, use a comma delimited string

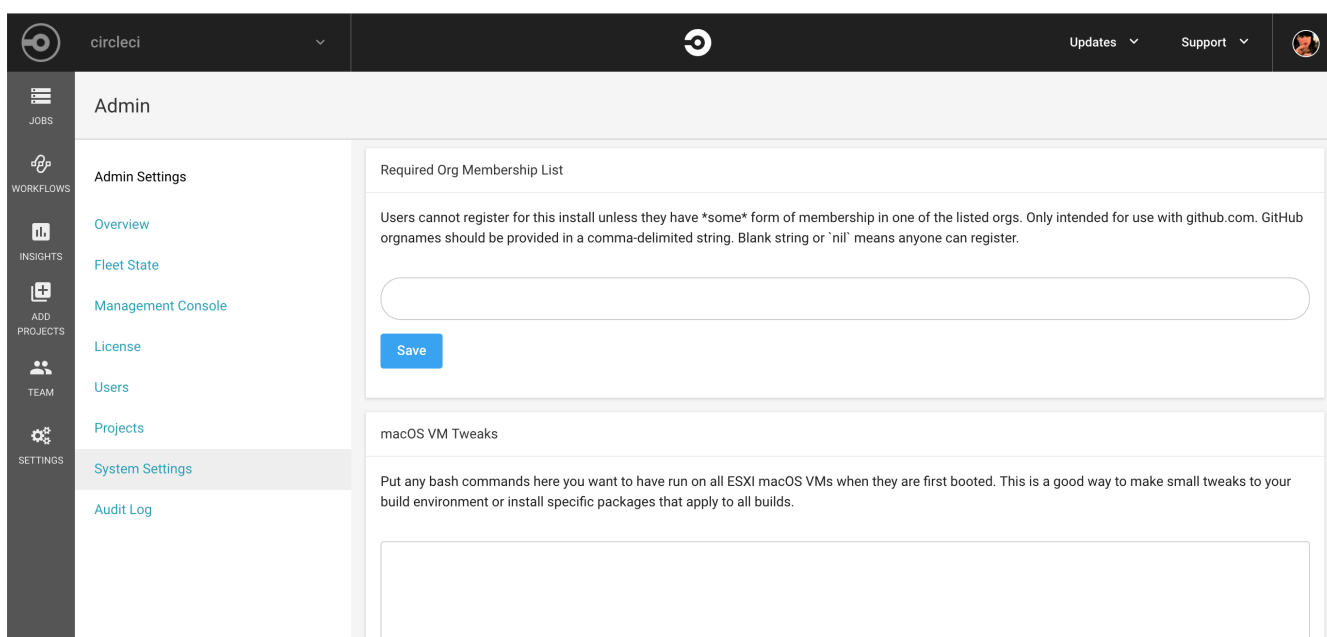

Figure 8. Organization Membership

Any form of organization membership is within the scope of this approval feature, and it does not stop users from running builds associated with other organizations they may belong to.

## Full User List

To view a full list of users for your CircleCI Server installation, first SSH into your Services machine, and then run:

```
circleci dev-console  
(circle.model.user/where { :$and [{:sign_in_count {:$gte 0}}, {:login {  
:$ne nil}}]} :only [:login])
```

## Deleting a User

If you need to remove a user from your installation of CircleCI Server, you will need to SSH into the services machine first and then delete using the following command, substituting the user's github username:

```
circleci dev-console  
(circle.http.api.admin-commands.user/delete-by-login-vcs-type! "github-  
username-of-user" :github)
```

# Build Artifacts

Build artifacts persist data after a job is completed and may be used for longer-term storage of your build process outputs. For example, when a Java build/test process finishes, the output of the process is saved as a `.jar` file. CircleCI can store this file as an artifact, keeping it available long after the process has finished.

# Safe and Unsafe Content Types

By default, CircleCI Server only allows whitelisted artifact types to be served. This is to protect users from uploading, and potentially executing malicious content. The whitelist is as follows:

Category	Safe Type
Text	Plain
Application	json
Image	png
Image	jpg
Image	gif
Image	bmp
Video	webm
Video	ogg
Video	mp4
Audio	webm
Audio	aac
Audio	mp4
Audio	mpeg
Audio	ogg
Audio	wav

Also, by default, the following types will be rendered as plain text:

Category	Type
Text	html
Text	css
Text	javascript
Text	ecmascript
Application	javascript
Application	ecmascript
Text	xml

# Allow Unsafe Content types

If you would like to allow content types that are not included in the whitelist above, follow these steps:

1. Navigate to the CircleCI Management Console (e.g. <https://<your-circleci-hostname>:8800/settings>) and select Settings from the menu bar
2. Scroll down to find the Artifacts section
3. Select Serve Artifacts with Unsafe Content-Types
4. Click Save at the bottom of the page and Restart Now in the pop-up to save your changes and restart the console.

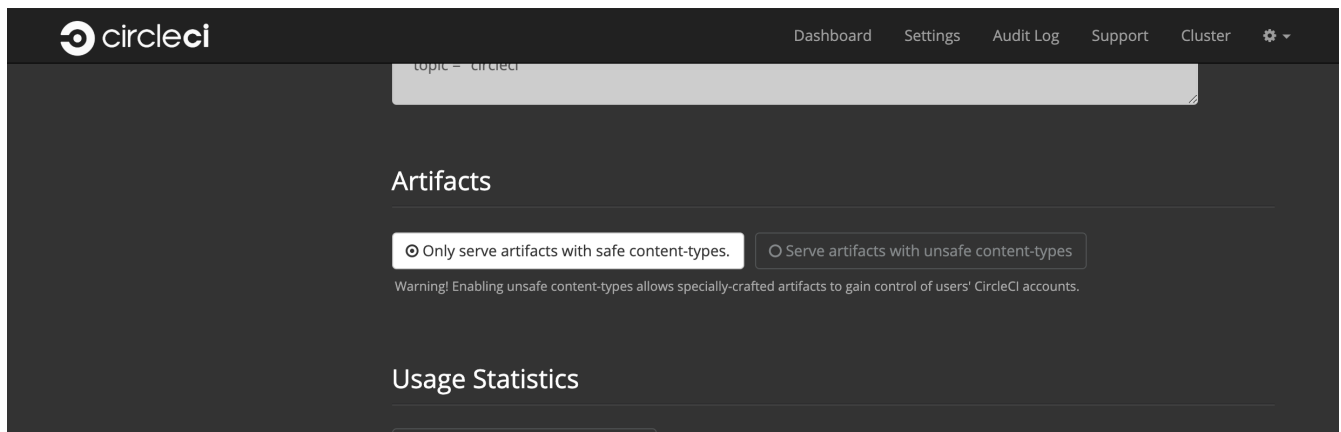

Figure 9. Allow Unsafe Content Types

Any change to the settings within the Management Console will incur downtime as the console will need to be restarted. = Enabling Usage Statistics :page-layout: classic-docs :page-liquid: :icons: font :toc: macro :toc-title:

This chapter is for System Administrators who want to automatically send some aggregate usage statistics to CircleCI. Usage statistics data enhances visibility into CircleCI installations and is used to better support you and ensure a smooth transition from CircleCI 1.0 to CircleCI 2.0.

To opt-in to this feature, navigate to your Management Console settings (e.g. <http://<circleci-hostname>.com:8800/settings>) and scroll down to Usage Statistics. Enable the radio button labeled Automatically send some usage statistics to CircleCI, as shown below.

## Artifacts

☒ Only serve artifacts with safe content-types.

☐ Serve artifacts with unsafe content-types

Warning! Enabling unsafe content-types allows specially-crafted artifacts to gain control of users' CircleCI accounts.

## Usage Statistics

☒ Automatically send some usage statistics to CircleCI

## License Agreement

By checking the box below, you certify that you have read and agree to the [CircleCI license agreement](#), and that you have the authority to agree to it on behalf of your company.

☒ I Agree

Save

# Detailed Usage Statistics

The following sections provide information about the usage statistics CircleCI will gather when this setting is enabled.

## Weekly Account Usage

Name	Type	Purpose
account_id	UUID	Uniquely identifies each vcs account
usage_current_macos	minutes	For each account, track weekly builds performed in minutes.
usage_legacy_macos	minutes	
usage_current_linux	minutes	
usage_legacy_linux	minutes	

## Weekly Job Activity

Name	Type	Purpose
utc_week	date	Identifies which week the data below applies to
usage_oss_macos_legacy	minutes	Track builds performed by week
usage_oss_macos_current	minutes	
usage_oss_linux_legacy	minutes	
usage_oss_linux_current	minutes	
usage_private_macos_legacy	minutes	
usage_private_macos_current	minutes	
usage_private_linux_legacy	minutes	
usage_private_linux_current	minutes	
new_projects_oss_macos_legacy	sum	Captures new Builds performed on 1.0. Observe if users are starting new projects on 1.0.
new_projects_oss_macos_current	sum	
new_projects_oss_linux_legacy	sum	
new_projects_oss_linux_current	sum	
new_projects_private_macos_legacy	sum	
new_projects_private_macos_current	sum	
new_projects_private_linux_legacy	sum	
new_projects_private_linux_current	sum	
projects_oss_macos_legacy	sum	Captures Builds performed on 1.0 and 2.0. Observe if users are moving towards 2.0 or staying with 1.0.
projects_oss_macos_current	sum	
projects_oss_linux_legacy	sum	
projects_oss_linux_current	sum	
projects_private_macos_legacy	sum	
projects_private_macos_current	sum	
projects_private_linux_legacy	sum	
projects_private_linux_current	sum	

# Accessing Usage Data

If you would like programatic access to this data in order to better understand your users you may run this command from the Services VM.

```
docker exec usage-stats /src/builds/extract
```

## Security and Privacy

Please reference exhibit C within your terms of contract and our [standard license agreement](<https://circleci.com/outer/legal/enterprise-license-agreement.pdf>) for our complete security and privacy disclosures. = Backup and Recovery :page-layout: classic-docs :page-liquid: :icons: font :toc: macro :toc-title:

This chapter describes failover or replacement of the services machine. Refer to the Backup section below for information about possible backup strategies and procedures for implementing a regular backup image or snapshot of the services machine.

# Disaster Recovery

Specify a spare machine, in an alternate location, with the same specs for disaster recovery of the services machine. Having a hot spare regularly imaged with the backup snapshot in a failure scenario is best practice.

At the very least, provide systems administrators of the CircleCI installation with the hostname and location (even if co-located) of an equivalent server on which to install a replacement server with the latest snapshot of the services machine configuration. To complete recovery, use the Installation procedure, replacing the image from that procedure with your backup image.

# Backing up CircleCI Data

This document describes how to back up your CircleCI application so that you can recover from accidental or unexpected loss of CircleCI data attached to the Services machine:

If you are running CircleCI in an HA configuration, you must use standard backup mechanisms for the external datastores. Contact [support@circleci.com](mailto:support@circleci.com) for more information document for more information.

# Backing up the Database

If you have **not** configured CircleCI for external services, the best practice for backing up your CircleCI data is to use VM snapshots of the virtual disk acting as the root volume for the Services machine. Backups may be performed without downtime as long the underlying virtual disk supports such an operation as is true with AWS EBS. There is a small risk, that varies by filesystem and distribution, that snapshots taken without a reboot may have some data corruption, but this is rare in practice.

"Snapshots Disabled" refers to Replicated's built-in snapshot feature that is turned off by default.

# Backing up Object Storage

Build artifacts, output, and caches are generally stored in object storage services like AWS S3. These services are considered highly redundant and are unlikely to require separate backup. An exception is if your instance is setup to store large objects locally on the Services machine, either directly on-disk or on an NFS volume. In this case, you must separately back these files up and ensure they are mounted back to the same location on restore.

# Snapshotting on AWS EBS

There are a few features of AWS EBS snapshots that make the backup process quite easy:

1. To take a manual backup, choose the instance in the EC2 console and select Actions > Image > Create Image.
2. Select the No reboot option if you want to avoid downtime. An AMI that can be readily launched as a new EC2 instance for restore purposes is created.

It is also possible to automate this process with the AWS API. Subsequent AMIs/snapshots are only as large as the difference (changed blocks) since the last snapshot, such that storage costs are not necessarily larger for more frequent snapshots, see [Amazon's EBS snapshot billing](#) document for details.

# Restoring From Backup

When restoring test backups or performing a restore in production, you may need to make a couple of changes on the newly launched instance if its public or private IP addresses have changed:

1. Launch a fresh EC2 instance using the newly generated AMI from the previous steps
2. Stop the app in the Management Console (at port 8800) if it is already running
3. Ensure that the hostname configured in the Management Console at port 8800 reflects the correct address. If this hostname has changed, you will also need to change it in the corresponding GitHub OAuth application settings or create a new OAuth app to test the recovery and log in to the application.
4. Update any references to the backed-up instance's public and private IP addresses in `/etc/default/replicated` and `/etc/default/replicated-operator` on Debian/Ubuntu or `/etc/sysconfig/*` in RHEL/CentOS to the new IP addresses.
5. From the root directory of the Services box, run `sudo rm -rf /opt/nomad`. State is saved in the `/opt/nomad` folder that can interfere with builds running when an installation is restored from a backup. The folder and its contents will be regenerated by Nomad when it starts.
6. Restart the app in the Management Console at port 8800.

# Cleaning up Build Records

While filesystem-level data integrity issues are rare and preventable, there will likely be some data anomalies in a point-in-time backup taken while builds are running on the system. For example, a build that is only half-way finished at backup time may result in missing the latter half of its command output, and it may permanently show that it is in Running state in the application.

If you want to clean up any abnormal build records in your database after a recovery, you can delete them by running the following commands on the Services machine replacing the example build URL with an actual URL from your CircleCI application:

```
$ circleci dev-console
# Wait for console to load
user=> (admin/delete-build "https://my-circleci-hostname.com/gh/my-
org/my-project/1234")
```

# Security

This document outlines security features built into CircleCI and related integrations.

# Overview

Security is our top priority at CircleCI, we are proactive and we act on security issues immediately. Report security issues to [security@circleci.com](mailto:security@circleci.com) with an encrypted message using our security team's GPG key (ID: 0x4013DDA7, fingerprint: 3CD2 A48F 2071 61C0 B9B7 1AE2 6170 15B8 4013 DDA7).

# Encryption

CircleCI uses HTTPS or SSH for all networking in and out of our service including from the browser to our services application, from the services application to your builder fleet, from our builder fleet to your source control system, and all other points of communication. In short, none of your code or data travels to or from CircleCI without being encrypted unless you have code in your builds that does so at your discretion. Operators may also choose to go around our SSL configuration or not use TLS for communicating with underlying systems.

The nature of CircleCI is that our software has access to your code and whatever data that code interacts with. All jobs on CircleCI run in a sandbox (specifically, a Docker container or an ephemeral VM) that stands alone from all other builds and is not accessible from the Internet or from your own network. The build agent pulls code via git over SSH. Your particular test suite or job configurations may call out to external services or integration points within your network, and the response from such calls will be pulled into your jobs and used by your code at your discretion. After a job is complete, the container that ran the job is destroyed and rebuilt. All environment variables are encrypted using [Hashicorp Vault](#). Environment variables are encrypted using AES256-GCM96 and are unavailable to CircleCI employees.

# Sandboxing

With CircleCI you control the resources allocated to run the builds of your code. This will be done through instances of our builder boxes that set up the containers in which your builds will run. By their nature, build containers will pull down source code and run whatever test and deployment scripts are part of the code base or your configuration. The containers are sandboxed, each created and destroyed for one build only (or one slice of a parallel build), and they are not available from outside themselves. The CircleCI service provides the ability to SSH directly to a particular build container. When doing this a user will have complete access to any files or processes being run inside that build container, so provide access to CircleCI only to those also trusted with your source code.

# Integrations

A few different external services and technology integration points touch CircleCI. The following list enumerates those integration points.

- **Web Sockets** We use [Pusher](#) client libraries for WebSocket communication between the server and the browser, though for installs we use an internal server called slanger, so Pusher servers have no access to your instance of CircleCI nor your source control system. This is how we, for instance, update the builds list dynamically or show the output of a build line-by-line as it occurs. We send build status and lines of your build output through the web socket server (which unless you have configured your installation to run without SSL is done using the same certs over SSL), so it is encrypted in transit.
- **Replicated** We use [Replicated](#) to manage the installation wizard, licensing keys, system audit logs, software updates, and other maintenance and systems tasks for CircleCI. Your instance of CircleCI communicates with Replicated servers to send license key information and version information to check for updates. Replicated does not have access to your data or other systems, and we do not send any of your data to Replicated.
- **Source Control Systems** To use CircleCI you will set up a direct connection with your instance of GitHub Enterprise or GitHub.com. When you set up CircleCI you authorize the system to check out your private repositories. You may revoke this permission at any time through your GitHub application settings page and by removing Circle's Deploy Keys and Service Hooks from your repositories' Admin pages. While CircleCI allows you to selectively build your projects, GitHub's permissions model is "all or nothing" — CircleCI gets permission to access all of a user's repositories or none of them. Your instance of CircleCI will have access to anything hosted in those git repositories and will create webhooks for a variety of events (eg: when code is pushed, when a user is added, etc.) that will call back to CircleCI, triggering one or more git commands that will pull down code to your build fleet.
- **Dependency and Source Caches** Most CircleCI customers use S3 or equivalent cloud-based storage inside their private cloud infrastructure (Amazon VPC, etc) to store their dependency and source caches. These storage servers are subject to the normal security parameters of anything stored on such services, meaning in most cases our customers prevent any outside access.
- **Artifacts** It is common to use S3 or similar hosted storage for artifacts. Assuming these resources are secured per your normal policies they are as safe from any outside intrusion as any other data you store there.
- **iOS Builds** If you are paying to run iOS builds on CircleCI hardware your source code will be downloaded to a build box on our macOS fleet where it will be compiled and any tests will be run. Similar to our primary build containers that you control, the iOS builds we run are sandboxed such that they cannot be accessed.

# Audit Logs

The Audit Log feature is only available for CircleCI installed on your servers or private cloud.

CircleCI logs important events in the system for audit and forensic analysis purposes. Audit logs are separate from system logs that track performance and network metrics.

Complete Audit logs may be downloaded from the Audit Log page within the Admin section of the application as a CSV file. Audit log fields with nested data contain JSON blobs.

**Note:** In some situations, the internal machinery may generate duplicate events in the audit logs. The **id** field of the downloaded logs is unique per event and can be used to identify duplicate entries.

## Audit Log Events

Following are the system events that are logged. See **action** in the Field section below for the definition and format.

- context.create
- context.delete
- context.env\_var.delete
- context.env\_var.store
- project.env\_var.create
- project.env\_var.delete
- project.settings.update
- user.create
- user.logged\_in
- user.logged\_out
- workflow.job.approve
- workflow.job.finish
- workflow.job.scheduled
- workflow.job.start

## Audit Log Fields

- **action:** The action taken that created the event. The format is ASCII lowercase words separated by dots, with the entity acted upon first and the action taken last. In some cases entities are nested, for example, **workflow.job.start**.
- **actor:** The actor who performed this event. In most cases this will be a CircleCI user. This data is a JSON blob that will always contain **id** and **type** and will likely contain **name**.
- **target:** The entity instance acted upon for this event, for example, a project, an org, an account, or a build. This data is a JSON blob that will always contain **id** and **type** and will likely contain **name**.

- **payload:** A JSON blob of action-specific information. The schema of the payload is expected to be consistent for all events with the same **action** and **version**.
- **occurred\_at:** When the event occurred in UTC expressed in ISO-8601 format with up to nine digits of fractional precision, for example '2017-12-21T13:50:54.474Z'.
- **metadata:** A set of key/value pairs that can be attached to any event. All keys and values are strings. This can be used to add additional information to certain types of events.
- **id:** A UUID that uniquely identifies this event. This is intended to allow consumers of events to identify duplicate deliveries.
- **version:** Version of the event schema. Currently the value will always be 1. Later versions may have different values to accommodate schema changes.
- **scope:** If the target is owned by an Account in the CircleCI domain model, the account field should be filled in with the Account name and ID. This data is a JSON blob that will always contain **id** and **type** and will likely contain **name**.
- **success:** A flag to indicate if the action was successful.
- **request:** If this event was triggered by an external request this data will be populated and may be used to connect events that originate from the same external request. The format is a JSON blob containing **id** (the request ID assigned to this request by CircleCI), **ip\_address** (the original IP address in IPV4 dotted notation from which the request was made, eg. 127.0.0.1), and **client\_trace\_id** (the client trace ID header, if present, from the 'X-Client-Trace-Id' HTTP header of the original request).

This document describes an initial set of troubleshooting steps to take if you are having problems with your CircleCI installation on your private server. If your issue is not addressed below, please [generate a support bundle](#) and contact our Support Engineers by [opening a support ticket](#).

# Debugging Queuing Builds

If your Services component is fine, but builds are not running, or all builds are queueing, follow the steps below.

## 1. Check Dispatcher Logs for Errors

Run `sudo docker logs dispatcher`, if you see log output that is free of errors you may continue on the next step.

If the logs dispatcher container does not exist or is down, start it by running the `sudo docker start <container_name>` command and monitor the progress. The following output indicates that the logs dispatcher is up and running correctly:

```
Jan 4 22:38:38.589:+0000 INFO circle.backend.build.run-queue dispatcher
mode is on - no need for

run-queue
Jan 4 22:38:38.589:+0000 INFO circle.backend.build.usage-queue
5a4ea0047d560d00011682dc:

GERey/realitycheck/37 -> forwarded to run-queue
Jan 4 22:38:38.589:+0000 INFO circle.backend.build.usage-queue
5a4ea0047d560d00011682dc: publishing

:usage-changed (:recur) event

Jan 4 22:38:39.069:+0000 INFO circle.backend.build.usage-queue got
usage-queue event for

5a4ea0047d560d00011682dc (finished-build)
```

If you see errors or do not see the above output, investigate the stack traces because they indicate that there is an issue with routing builds from 1.0 to 2.0. If there are errors in the output, then you may have a problem with routing builds to 1.0 or 2.0 builds.

If you can run 1.0 builds, but not 2.0 builds, or if you can only run 2.0 builds and the log dispatcher is up and running, continue on to the next steps.

## 2. Check Picard-Dispatcher Logs for Errors

Run the `sudo docker logs picard-dispatcher` command. A healthy `picard-dispatcher` should output the following:

```

Jan 9 19:32:33 INFO picard-dispatcher.init Still running...
Jan 9 19:34:33 INFO picard-dispatcher.init Still running...
Jan 9 19:34:44 INFO picard-dispatcher.core taking build
=GERey/realitycheck/38
Jan 9 19:34:45 INFO circle.http.builds project GERey/realitycheck at
revision

2c6179654541ee3d succcessfully fetched and parsed .circleci/config.yml

picard-dispatcher.tasks build GERey/realitycheck/38 is using resource

class {:cpu 2.0, :ram 4096, :class :medium}
picard-dispatcher.tasks Computed tasks for build=GERey/realitycheck/38,

stage=:write_artifacts, parallel=1
Jan 9 19:34:45 INFO picard-dispatcher.tasks build has matching jobs:

build=GERey/realitycheck/38 parsed=:write_artifacts passed
=:write_artifacts

```

The output should be filled with the above messages. If it is a slow day and builds are not happening very often, the output will appear as follows:

```

Jan 9 19:32:33.629:+0000 INFO picard-dispatcher.init Still running...

```

As soon as you run a build, you should see the above message to indicate that it has been dispatched to the scheduler. If you do not see the above output or you have a stack trace in the picard-dispatcher container, contact [support@circleci.com](mailto:support@circleci.com).

If you run a 2.0 build and do not see a message in the picard-dispatcher log output, it often indicates that a job is getting lost between the dispatcher and the picard dispatcher.

Stop and restart the CircleCI app in the Management Console at port 8800 to re-establish the connection between the two containers.

### 3. Check Picard-Scheduler Logs for Errors

Run `sudo docker logs picard-scheduler`. The `picard-scheduler` schedules jobs and sends them to nomad through a direct connection. It does not actually handle queuing of the jobs in CircleCI.

## 4. Check Nomad Node Status

Check to see if there are any nomad nodes by running the `nomad node-status -allocs` command and viewing the following output:

ID	DC	Name	Class	Drain	Status	Allocs
ec2727c5	us-east-1	ip-127-0-0-1	linux-64bit	false	ready	0

If you do not see any nomad clients listed, please consult our <nomad#,Introduction to Nomad Cluster Operation> for more detailed information on managing and troubleshooting the nomad server.

DC in the output stands for datacenter and will always print us-east-1 and should be left as such. It doesn't affect or break anything. The things that are the most important are the Drain, Status, and Allocs columns.

- **Drain** - If **Drain** is **true** then CircleCI will **not** route jobs to that nomad client. It is possible to change this value by running the following command `nomad node-drain [options] <node>`. If you set Drain to **true**, it will finish the jobs that were currently running and then stop accepting builds. After the number of allocations reaches 0, it is safe to terminate instance. If **Drain** is set to **false** it means the node is accepting connections and should be getting builds.
- **Status** - If Status is **ready** then it is ready to accept builds and should be wired up correctly. If it is not wired up correctly it will not show **ready** and it should be investigated because a node that is not showing **ready** in the Status will not accept builds.
- **Allocs** - Allocs is a term used to refer to builds. So, the number of Running Allocs is the number of builds running on a single node. This number indicates whether builds are routing. If all of the Builders have Running Allocs, but your job is still queued, that means you do not have enough capacity and you need to add more Builders to your fleet.

If you see output like the above, but your builds are still queued, then continue to the next step.

## 5. Check Job Processing Status

Run the `sudo docker exec -it nomad nomad status` command to view the jobs that are currently being processed. It should list the status of each job as well as the ID of the job, as follows:

ID	Type	Priority
Status		
5a4ea06b7d560d000116830f-0-build-GERey-realitycheck-1	batch	50
dead		
5a4ea0c9fa4f8c0001b6401b-0-build-GERey-realitycheck-2	batch	50
dead		
5a4ea0cafa4f8c0001b6401c-0-build-GERey-realitycheck-3	batch	50
dead		

After a job has completed, the Status shows **dead**. This is a regular state for jobs. If the status shows **running**, the job is currently running. This should appear in the CircleCI app builds dashboard. If it is not appearing in the app, there may be a problem with the output-processor. Run the **docker logs picard-output-processor** command and check the logs for any obvious stack traces.

- If the job is in a constant **pending** state with no allocations being made, run the **sudo docker exec -it nomad nomad status JOB\_ID** command to see where Nomad is stuck and then refer to standard Nomad Cluster error documentation for information.
- If the job is running/dead but the CircleCI app shows nothing:
  - ❓ Check the Nomad job logs by running the **sudo docker exec -it nomad nomad logs --stderr --job JOB\_ID** command.
  - ❓ Run the **picard-output-processor** command to check those logs for specific errors.

The use of **--stderr** is to print the specific error if one exists.

## Jobs stay in **queued** status until they fail and never successfully run

If the nomad client logs contain the following error message typw, check port 8585:

```
{"error":"rpc error: code = Unavailable desc = grpc: the connection is
unavailable", "level":"warning", "msg":"error fetching config, retrying"
, "time":"2018-04-17T18:47:01Z"}
```

# Why is the cache failing to unpack?

If a `restore_cache` step is failing for one of your jobs, it is worth checking the size of the cache - you can view the cache size from the CircleCI Jobs page within the `restore_cache` step. We recommend keeping cache sizes under 500MB - this is our upper limit for corruption checks because above this limit check times would be excessively long. Larger cache sizes are allowed but may cause problems due to a higher chance of decompression issues and corruption during download. To keep cache sizes down, consider splitting into multiple distinct caches.

# How do I get round the API service being impacted by a high thread count

Disable cache warming by completing the following steps:

1. Add the export `DOMAIN_SERVICE_REFRESH_USERS=false` flag to the ``/etc/circleconfig/api-service/customizations` file on the Services machine. For more information on configuration overrides, see <server-config-overrides#\_server\_config\_overrides,Server Config Overrides>.
2. Restart CircleCI:
  1. Navigate to the Management Console
  2. Click Stop Now and wait for it to stop
  3. Click Start
